A significant portion of [data](#) in [Electronic Health Records](#) is only available as unstructured [text](#), such as surgical or finding [reports](#), clinical notes, and discharge summaries. To use this data for secondary purposes, [natural language processing](#) (NLP) tools are required to extract structured information. Furthermore, for interoperable use, [harmonization](#) of the data is necessary. HL7 [Fast Healthcare Interoperability Resources](#) (FHIR), an emerging standard for exchanging [healthcare data](#), defines such a structured format. For German-language medical NLP, the tool [Averbis Health Discovery](#) (AHD) represents a comprehensive solution. AHD offers a proprietary REST interface for text analysis pipelines. To build a bridge between FHIR and this interface, we created a service that translates the communication around AHD from and to FHIR. The application is available under an open-source license <sup>1)</sup>.
