

# Dominant hemisphere

see [Hemispheric Dominance](#)

The dominant hemisphere refers to the side of the brain primarily responsible for certain higher-order functions, particularly [language](#) and fine [motor skills](#). In most individuals, the left hemisphere is dominant, but this can vary based on handedness and individual differences.

Key Functions of the Dominant Hemisphere: Language and Communication:

Speech production (Broca's area) Language comprehension (Wernicke's area) Reading and writing  
Fine Motor Control:

Skilled motor movements, especially in the dominant hand Logical and Analytical Thinking:

Mathematics, reasoning, and problem-solving Memory Related to Language:

Verbal memory and sequential processing Determining Dominance: The left hemisphere is dominant in about: 95% of right-handed individuals 70% of left-handed individuals The right hemisphere is dominant for language in a smaller proportion of left-handed individuals or those with atypical brain organization. Clinical Relevance: Stroke or Brain Injury: Damage to the dominant hemisphere often leads to significant deficits in language (aphasia) and fine motor skills. Epilepsy and Brain Surgery: Pre-surgical evaluations (e.g., Wada test, functional MRI) help identify the dominant hemisphere to preserve critical functions. Hemispheric Specialization: While the dominant hemisphere handles structured and logical tasks, the non-dominant hemisphere typically governs spatial awareness, creativity, and emotional processing.
