

**DYT5 (GCH1)**: Also known as Segawa syndrome, DYT5 is caused by mutations in the GCH1 gene. It usually starts in childhood with diurnal fluctuations in symptoms and responds well to levodopa.

#### Dystonia-Plus Syndromes:

Some genetic dystonias are associated with additional neurological features, leading to the classification of dystonia-plus syndromes.

**DYT11 (SGCE)**: This is associated with myoclonus and psychiatric symptoms and is known as myoclonus-dystonia syndrome.

#### Paroxysmal Dystonias:

Some forms of dystonia are paroxysmal, meaning they occur in episodes rather than being continuous. **DYT8 (PNKD)**: This form is associated with paroxysmal nonkinesigenic dyskinesia and can include dystonic movements during episodes. Dystonia with Neurodegeneration:

Some genetic forms of dystonia are associated with neurodegenerative features. **DYT3 (ATP1A3)**: Also known as rapid-onset dystonia-parkinsonism (RDP), this condition presents with abrupt onset dystonia and parkinsonism. It's important to note that genetic dystonias can be inherited in an autosomal dominant, autosomal recessive, or X-linked manner. Genetic testing is often employed to identify specific gene mutations associated with dystonia, providing valuable information for diagnosis and sometimes influencing treatment decisions
