

Echinococcus canadensis

The cestode [Echinococcus](#) canadensis belongs to the complex Echinococcus granulosus sensu lato. This parasite is a member of Cyclophyllidea which comprise the majority of tapeworms that are of medical importance. Adult *E. canadensis* parasitise the small intestines of dogs and other canids. The larval stage is one of the causative agents of the serious and life-threatening human disease cystic echinococcosis. *E. canadensis* has a worldwide distribution.

A study reports mitochondrial gene analysis from 4 Mongolian pediatric cerebral CE cases. Molecular confirmation was obtained for 3 of the 4 cases, with all 3 cases determined to be due to [Echinococcus canadensis](#) (G6/G7) infection. None of the cases had other organ involvement. This is only the third report on the molecular identification of the *Echinococcus* species responsible for [Cerebral echinococcosis](#), and only the second report of *E. canadensis* (G6/G7) being the causative agent of cerebral CE ¹⁾.
