

## Falx cerebri

The **falx cerebri**, also known as the cerebral falx, its a dural brain covering, so named from its sickle-like form, is a strong, arched fold of dura mater that descends vertically in the **longitudinal fissure** between the **cerebral hemispheres**.

It is narrow in front, where it is attached to the **crista galli** of the **ethmoid bone**; and broad behind, where it is connected with the upper surface of the **tentorium cerebelli**.

Its upper margin is convex, and attached to the inner surface of the skull in the middle line, as far back as the internal occipital protuberance; it contains the superior sagittal sinus. Its lower margin is free and concave, and contains the inferior sagittal sinus.

The falx cerebri is known to calcify with age.

The falx is a more reliable guide than the **anterior cerebral artery** ACA in completing the posterior part of the intraventricular callosotomy <sup>1)</sup>.
