

Fluorodeoxyglucose

FDG-PET

see [18F fluorocholine positron emission tomography](#)

see [18F positron emission tomography](#).

see [18F FET PET](#).

Fluorodeoxyglucose (**18F**) (INN), or [fluorodeoxyglucose F 18](#) (USAN and USP), also commonly called [fluorodeoxyglucose](#) and abbreviated [\[18F\]FDG](#), [18F-FDG](#) or [FDG](#), is a radiopharmaceutical used in the medical imaging modality [positron emission tomography](#) (PET). Chemically, it is 2-deoxy-2-[18F]fluoro-D-glucose, a glucose analog, with the positron-emitting [radionuclide fluorine-18](#) substituted for the normal hydroxyl group at the C-2 position in the glucose molecule.

The uptake of 18F-FDG by tissues is a marker for the tissue uptake of glucose, which in turn is closely correlated with certain types of tissue metabolism. After 18F-FDG is injected into a patient, a PET scanner can form two-dimensional or three-dimensional images of the distribution of 18F-FDG within the body.

Since its development in 1976, 18F-FDG had a profound influence on research in the neurosciences. The subsequent discovery in 1980 that 18F-FDG accumulates in tumors underpins the evolution of PET as a major clinical tool in cancer diagnosis.

[18F-FDG](#) is now the standard radiotracer used for PET neuroimaging and cancer patient management.

The images can be assessed by a nuclear medicine physician or radiologist to provide diagnoses of various medical conditions.
