

Intraosseous lipomatous meningioma

Intraosseous [lipomatous meningioma](#) are very uncommon subtype of [meningiomas](#), with ongoing discussions as to their true [pathogenesis](#).

A 49-year-old man with intermittent [headaches](#) and right sided parietal lump was found to have an intraosseous right parietal lesion on [computed tomography](#) (CT) and [magnetic resonance imaging](#) (MRI). A stereotactic [craniectomy](#) and excision of the lesion were performed with histopathology confirming features consistent with primary lipomatous meningioma with predominant intraosseous extension. To the knowledge of Kim et al. this case represents the first reported case of a lipomatous meningioma with predominant intraosseous extension ¹⁾.
