

Radiographic features

see [Intraventricular tumor diagnosis](#).

On the brain [MRI](#) with and without contrast, intraventricular meningioma appears as a solid, well-circumscribed mass, iso- or hypointense on T1 and T2-weighted images, and showing homogeneous contrast enhancement.

Their [signal](#) and attenuation characteristics are the same as other meningiomas, demonstrating essentially [isodense](#) and [intensity](#) to [grey matter](#) precontrast and vivid, usually homogeneous enhancement following administration of [contrast](#). Compared to [extra-axial](#) meningiomas, a greater proportion is calcified (50% compared to 20% for standard meningioma).

The vascular supply depends on the location but generally is from the arterial supply of the adjacent [choroid plexus](#)¹⁾.
