

Ischemic stroke epidemiology

Approximately 15% of [deaths](#) in a [developed country](#) are due to [sudden cardiac arrest](#), making it the most common cause of death worldwide. Though high-quality [cardiopulmonary resuscitation](#) has improved overall survival rates, the majority of survivors remain [comatose](#) after return of spontaneous circulation secondary to [hypoxic-ischemic brain injury](#). Since the advent of targeted temperature management, neurologic recovery has improved substantially, but the majority of patients are left with [neurologic deficits](#) ranging from minor [cognitive impairment](#) to persistent [coma](#). Of those who survive cardiac arrest, but die during their [hospitalization](#), some progress to [brain death](#) and others die after withdrawal of life-sustaining treatment due to anticipated poor neurologic [prognosis](#)¹⁾.

[Ischemic stroke](#) is a leading cause of [mortality](#) and [morbidity](#) worldwide, and [atherosclerosis](#) is one of the major risk factors for this neurologic deficit.

Only 3% of ischemic strokes occur in patients < 40 yrs of age²⁾. Over 10% of ischemic strokes occur in patients ≤ 55 yrs³⁾.

Incidence: 10 per 100,000 persons age 35–44 yrs, 22 per 100,000 for age < 55 yrs⁴⁾.
