

A 9-year-old male patient with a recurrent [fourth ventricle anaplastic ependymoma](#) who developed severe [arterial hypertension](#) and [blood pressure lability](#) during and after [surgery](#). A punctual bilateral [lesion](#) located within mid dorsal [medulla oblongata](#) caused by both infiltration and surgical [resection](#) was observed in postoperative [MRI](#). Three years later, the patient remained neurologically stable but the family referred the presence of a chronic [tachycardia](#) as well as [palpitations](#) and [sweating](#) with flushing episodes related to environmental stress. On autonomic evaluation, an increase in sympathetic outflow with tachycardia together with orthostatic hypotension caused by baroreceptor reflex dysfunction was observed. Martín-Gallego et al. postulate that a bilateral injury to both nuclei of the [solitary tract](#) may have caused central dysautonomia ¹⁾
