

# Mitochondrial function

**Mitochondria** are often referred to as the “powerhouses” of the **cell** because their primary function is to produce adenosine triphosphate (ATP), the molecule that provides energy for various cellular activities. However, mitochondria are involved in several other important functions within the cell:

**ATP Production:** The most well-known function of mitochondria is ATP synthesis through oxidative phosphorylation. This process involves the electron transport chain, where electrons are transferred through a series of protein complexes, ultimately leading to the production of ATP.

**Metabolism and Energy Conversion:** Mitochondria are central to cellular metabolism. They play a crucial role in breaking down nutrients such as glucose and fatty acids to generate ATP through cellular respiration. This process involves glycolysis in the cytoplasm and the citric acid cycle (Krebs cycle) within the mitochondrial matrix.

**Calcium Regulation:** Mitochondria are involved in regulating calcium ion concentrations within the cell. They can take up and release calcium ions, which is essential for various cellular processes, including muscle contraction and cell signaling.

**Apoptosis (Cell Death):** Mitochondria play a role in apoptosis, a programmed cell death process. When certain signals trigger apoptosis, mitochondria release molecules like cytochrome c, which activates caspase enzymes, leading to cell death.

**ROS Production:** While mitochondria are essential for energy production, they also generate reactive oxygen species (ROS) as byproducts. ROS can have both beneficial and harmful effects in cells. At low levels, they act as signaling molecules, but excessive ROS can cause oxidative stress and damage cellular components.

**Heat Production:** In certain specialized cells, mitochondria can generate heat rather than ATP through a process called thermogenesis. This is particularly important in brown adipose tissue, where it helps maintain body temperature in mammals.

**Lipid Synthesis:** Mitochondria are involved in lipid metabolism and can synthesize certain lipids, such as cardiolipin, a unique phospholipid found in the mitochondrial inner membrane.

**Heme Synthesis:** Mitochondria are essential for the synthesis of heme, a component of hemoglobin and various enzymes involved in oxygen transport and metabolism.

Mitochondrial dysfunction can have severe consequences for cell and tissue health. It is associated with various diseases, including mitochondrial disorders, neurodegenerative diseases, metabolic disorders, and cancer. Factors such as genetic mutations, environmental toxins, and aging can all impact mitochondrial function.

Understanding mitochondrial function is crucial for studying cellular physiology, metabolism, and disease mechanisms. Research into mitochondria continues to uncover their role in various aspects of biology and human health, making them a significant focus of scientific investigation.

---

Qin et al. employed a robust **computational framework** to investigate the **relationship** between mitochondrial function and 18 **cell death** patterns in a cohort of 1467 LGG patients from six

[multicenter cohorts](#) worldwide. A total of 10 commonly used [machine learning algorithms](#) were collected and subsequently combined into 101 unique combinations. Ultimately, we devised the mitochondria-associated [programmed cell death](#) index (mtPCDI) using machine learning models that exhibited optimal performance.

Results: The mtPCDI, generated by combining 18 highly influential genes, demonstrated strong predictive performance for prognosis in LGG patients. Biologically, mtPCDI exhibited a significant correlation with immune and metabolic signatures. The high mtPCDI group exhibited enriched metabolic pathways and a heightened immune activity profile. Of particular importance, our mtPCDI maintains its status as the most potent prognostic indicator even following adjustment for potential confounding factors, surpassing established clinical models in predictive strength.

The [utilization](#) of a robust [machine learning framework](#) highlights the significant potential of mtPCDI in providing personalized [risk assessment](#) and tailored [recommendations](#) for metabolic and [immunotherapy](#) interventions for individuals diagnosed with LGG. Of particular significance, the [signature](#) features highly influential [genes](#) that present further prospects for future [investigations](#) into the role of PCD within [mitochondrial function](#) <sup>1)</sup>.
