- State and trait anxiety and depression in patients with primary brain tumors before and after surgery: 1-year longitudinal study
- Quality of life after facial nerve repair

Compared to clinical observation only, patients who underwent [Vestibular Schwannoma surgery](#) were twice more likely and those who underwent SRS were 1.5 times more likely to develop [Mental Health Disorders](#) with a corresponding increase in health care utilization at one-year follow-up <sup>1)</sup>

[Gross Total resection](#) is associated with better [QoL](#) using the general QoL measures [SF-36](#) and [PROMIS-10](#) and the disease-specific PANQOL, even after controlling for baseline and outcome differences. This is especially significant in the assessment of [mental health](#), indicating there may indeed be a psychological advantage to the patient that translates to overall well-being to have the entire tumor removed if microsurgical [resection](#) is undertaken <sup>2)</sup>.
