

# Novice

A [study](#) outlines the first [investigation](#) of the application of [machine learning](#) to distinguish “[skilled](#)” and “[novice](#)” [psychomotor performance](#) during a [virtual reality](#) (VR) brain [tumor resection](#) task. Tumor resection [task](#) participants included 23 [neurosurgeons](#) and [senior neurosurgery residents](#) as the “[skilled](#)” group and 92 [junior](#) neurosurgery residents and [medical students](#) as the “[novice](#)” group. The [task](#) involved removing a series of virtual [brain tumors](#) without causing [injury](#) to surrounding tissue. Originally, 150 features were extracted followed by [statistical analysis](#) and forward feature selection. The selected features were provided to 4 classifiers, namely, K-Nearest Neighbors, Parzen Window, Support Vector Machine, and Fuzzy K-Nearest Neighbors. Sets of 5 to 30 selected features were provided to the classifiers. A working point of 15 premium features resulted in accuracy values as high as 90% using the Support Vector Machine. The obtained results highlight the potentials of machine learning, applied to VR simulation data, to help realign the traditional apprenticeship educational paradigm to a more objective model, based on proven performance standards. Graphical abstract Using several scenarios of virtual reality neurosurgical tumor resection together with machine learning classifiers to distinguish skill level <sup>1)</sup>.
