

# Insular subdivisions

The [insula](#), consisting of [functionally](#) diverse subdivisions, plays a significant role in [Parkinson's disease](#) (PD)-related [cognitive disorders](#). However, the [functional connectivity](#) (FC) patterns of insular subdivisions in PD remain unclear. The aim of Pan et al. is to investigate the changes in FC patterns of insular subdivisions and their relationships with [cognitive](#) domains. Three groups of participants were recruited in this [study](#), including PD patients with mild cognitive impairment (PD-MCI, n = 25), PD patients with normal [cognition](#) (PD-NC, n = 13), and healthy controls (HCs, n = 17). [Resting-state functional magnetic resonance imaging](#) (rs-fMRI) was used to investigate the FC in insular subdivisions of the three groups. Moreover, all participants underwent a neuropsychological battery to assess cognition so that the relationship between altered FC and cognitive performance could be elucidated. Compared with the PD-NC group, the PD-MCI group exhibited increased FC between the left [dorsal anterior insular](#) (dAI) and the right [superior parietal gyrus](#) (SPG), and altered FC was negatively correlated with [memory](#) and [executive function](#). Compared with the HC group, the PD-MCI group showed significantly increased FC between the right dAI and the right median [cingulate](#) and [paracingulate gyri](#) (DCG), and altered FC was positively related to [attention/working memory](#), [visuospatial function](#), and [language](#). The findings highlighted the different abnormal FC patterns of insular subdivisions in PD patients with different cognitive abilities. Furthermore, dysfunction of the dAI may partly contribute to the decline in executive function and memory in early drug-naïve PD patients <sup>1)</sup>.
