

# Petroclival region

The petroclival region is a small [cisternal](#) space located in the most anterior part of the [posterior cranial fossa](#).

It is defined by complex osteomeningeal edges but at the top, it opens onto the supratentorial sector, at the bottom onto the peribulbar area, and behind onto the area of the [cerebellopontine angle](#).

Numerous surgical approaches have been developed to access the petroclival region. The [Kawase approach](#), through the middle fossa, is a well-described option for addressing cranial base lesions of the petroclival region.

Early attempts to expose this region consisted primarily of an extended [suboccipital craniectomy](#), with opening of the [tentorium](#) and ligation of the [sigmoid sinus](#) for additional exposure. During the 1960s, technological innovations including the surgical [microscope](#) and the pneumatic drill allowed surgeons to gain additional exposure by removing more bone from the [skull base](#). This let surgeons define combined infra- and [supratentorial approaches](#), which rely less on [brain retraction](#) to resect these difficult tumors successfully. These approaches rely on a combined posterior [mastoid approach](#) with an anterior [petrosectomy](#)<sup>1)</sup>.

see [Sphenopetroclival region](#)
