

Phagosome

A **phagosome** is a membrane-bound **vesicle** formed around a **particle** engulfed by a phagocytic cell through the process of **phagocytosis**. Once internalized, the phagosome fuses with **lysosomes** to form a **phagolysosome**, where the contents are degraded by **enzymes**.

Phagosomes play a crucial **role** in the **innate immune response**, particularly in the clearance of **pathogens** and apoptotic cells. In the context of **glioblastoma (GB)**, changes in **phagosome-related protein expression** may reflect alterations in **immune surveillance**, **tumour-associated macrophage activity**, and **neuroinflammatory mechanisms**.

Recent studies, such as those by Liu et al. have linked **phagosome pathways** to potential **biomarker candidates** in GB, suggesting a role in disease progression and tumour-host interactions
