

Quantitative magnetic resonance imaging

The immunological pathophysiologies of [chronic inflammatory demyelinating polyneuropathy](#) (CIDP) and [multifocal motor neuropathy](#) (MMN) differ considerably, but neither has been elucidated completely. Quantitative [magnetic resonance imaging](#) (MRI) techniques as [diffusion tensor imaging](#), [T2 mapping](#), and [fat fraction](#) analysis may indicate in vivo pathophysiological changes in nerve architecture.

A study of van Rosmalen et al. aimed to [systematically](#) study [nerve](#) architecture of the [brachial plexus](#) in patients with CIDP, MMN, [motor neuron disease](#) (MND) and healthy controls using these quantitative MRI techniques.

They enrolled patients with CIDP (n = 47), MMN (n = 29), MND (n = 40) and healthy controls (n = 10). All patients underwent MRI of the brachial plexus and obtained diffusion parameters, T2 relaxation times and fat fraction using an automated processing pipeline. They compared these parameters between groups using a univariate general linear model.

[Fractional anisotropy](#) was lower in patients with CIDP compared to healthy controls ($p < 0.001$), patients with MND ($p = 0.010$) and MMN ($p < 0.001$). Radial diffusivity was higher in patients with CIDP compared to healthy controls ($p = 0.015$) and patients with MND ($p = 0.001$) and MMN ($p < 0.001$). T2 relaxation time was elevated in patients with CIDP compared to patients with MND ($p = 0.023$). Fat fraction was lower in patients with CIDP and MMN compared to patients with MND (both $p < 0.001$).

These results show that quantitative MRI parameters differ between CIDP, MMN and MND, which may reflect differences in underlying pathophysiological mechanisms ¹⁾.
