

see [Serum Osmolality](#)

Fluid management is an important component of [perioperative care](#) for patients undergoing [neurosurgery](#). The primary goal of fluid [management](#) in neurosurgery is the maintenance of [normovolemia](#) and prevention of [serum osmolarity](#) reduction. To maintain normovolemia, it is important to administer [fluids](#) in appropriate amounts following appropriate [methods](#), and to prevent a decrease in serum osmolarity, the choice of fluid is essential. There is considerable debate about the choice and optimal amounts of fluids administered in the perioperative period. However, there is little high-quality [clinical research](#) on [fluid therapy](#) for patients undergoing neurosurgery. A review of Ryu discussed the choice and optimal amounts of fluids in neurosurgical [patients](#) based on the [literature](#), recent [issues](#), and perioperative fluid management practices <sup>1)</sup>.
