

Image guidance in open [spinal surgery](#) is compromised by changes in [spinal alignment](#) between [preoperative](#) images and surgical [positioning](#). Fan et al. evaluated the registration of stereo-views of the surgical field to compensate for vertebral alignment changes.

To assess the accuracy and efficiency of an optically tracked hand-held [stereovision](#) (HHS) system to acquire images of the exposed spine during surgery.

The standard midline posterior approach exposed L1 to L6 in 6 cadaver porcine spines. [Fiducial](#) markers were placed on each vertebra as “ground truth” locations. [Spines](#) were positioned [supine](#) with accentuated [lordosis](#), and preoperative [computed tomography](#) (pCT) was acquired. Spines were re-positioned in a neutral [prone](#) posture, and locations of [fiducials](#) were acquired with a tracked stylus. Intraoperative [stereovision](#) (iSV) images were acquired and 3-dimensional (3D) surfaces of the exposed spine were reconstructed. HHS accuracy was assessed in terms of distances between reconstructed fiducial marker locations and their tracked counterparts. Level-wise registrations aligned pCT with iSV to account for changes in spine posture. Accuracy of updated [computed tomography](#) (uCT) was assessed using fiducial markers and other [landmarks](#).

The acquisition time for each image pair was <1 s. Mean reconstruction time was <1 s for each image pair using batch processing, and mean accuracy was  $1.2 \pm 0.6$  mm across 6 cases. Mean errors of uCT were  $3.1 \pm 0.7$  and  $2.0 \pm 0.5$  mm on the dorsal and ventral sides, respectively.

Results suggest that a portable HHS system offers the potential to acquire accurate image data from the surgical field to facilitate surgical navigation during open spine surgery <sup>1)</sup>.
