

Neurogenic claudication symptoms are typically **posture**-related; symptoms are aggravated when the spine is extended (in upright stance) but eased when spine is flexed (sitting or lying **supine**) ¹⁾.

The theory behind the syndrome is that the exacerbation results from dynamic stenoses, such as in **degenerative spondylolisthesis**, which causes posture-related compression. Typically, patients experience relief by **spine flexion**, when there is indirect decompression of the neural elements at the stenotic motion segment.
