

Syndrome of inappropriate antidiuretic hormone secretion diagnosis

Essential features

- decreased effective serum osmolality (<275 mOsm/kg of water)

- simultaneous urine osmolality >100 mOsm/kg of water

- clinical euvolemia

a) no clinical signs of extracellular (EC) volume orthostatic hypotension (orthostasis, tachycardia, decreased skin turgor, dry mucous membranes...)

b) no clinical signs of excess EC volume (edema, ascites...)

- urinary $[\text{Na}] >40$ mEq/L with normal dietary Na intake

- normal thyroid and adrenal function

- no recent diuretic use

Supplemental features

- plasma $[\text{uric acid}] <4$ mg/dl

- $[\text{BUN}] <10$ mg/dl

- fractional Na excretion $>1\%$; fractional urea excretion $>55\%$

- NS infusion test: failure to correct hyponatremia with IV infusion of 2L 0.9% saline over 24–48hrs

- correction of hyponatremia with fluid restriction

- abnormal result on water load tests:

a) $<80\%$ excretion of 20 ml of water/kg body weight over 5 hours, or

b) inadequate urinary dilution (<100 mOsm/kg of water) ● elevated plasma $[\text{ADH}]$ with hyponatremia and euvolemia

a effective osmolality (AKA tonicity) = (measured osmolality) - $[\text{BUN}]/2.8$ with $[\text{BUN}]$ measured in mg/dl

b this test is used in uncertain cases (corrects volume depletion) and is usually safe when baseline urine osmolality is <500 mOsm/L

c water load test & $[\text{ADH}]$ levels are rarely recommended.
