Metastases to the **temporal lobe** refer to the spread of **cancer** from a primary tumor to the temporal lobe of the brain. The temporal lobe is a region of the brain located on the side of the head, near the temples, and is involved in many functions including memory, language, and hearing.

Symptoms of temporal lobe metastases may include headaches, seizures, changes in vision or hearing, difficulty with memory or language, and weakness or numbness on one side of the body. These symptoms can vary depending on the size and location of the metastases.

Treatment options for temporal lobe metastases depend on the size, location, and extent of the cancer, as well as the overall health of the patient. Treatment may include surgery, radiation therapy, chemotherapy, or a combination of these approaches.

Overall, the prognosis for patients with temporal lobe metastases is generally poor, as these metastases often indicate advanced stage cancer. However, with early detection and appropriate treatment, some patients may experience improved outcomes and quality of life.
